Template Method Pattern

---

# The Template-Method Pattern in a Nutshell

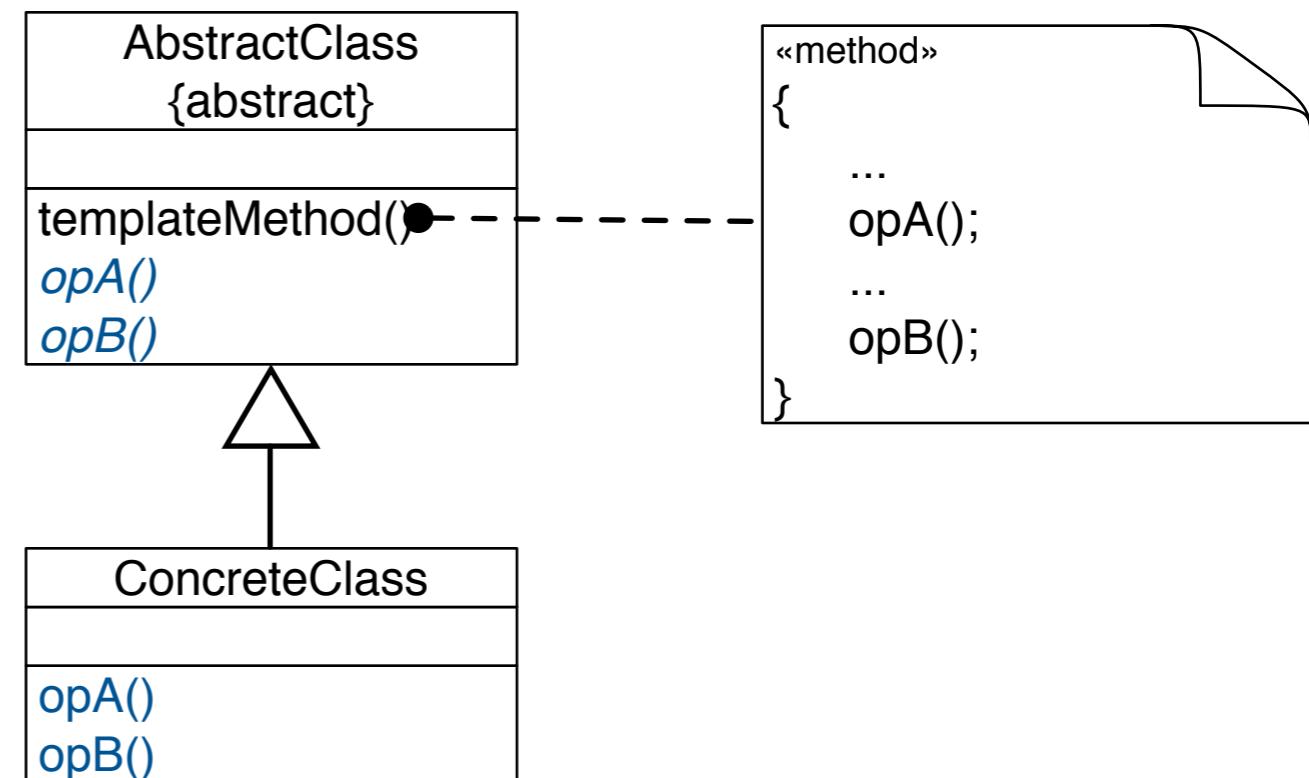

## Intent:

- Separate high-level policies from detailed low-level mechanisms.
- Separate invariant from variant parts.

## Solution Idea:

Use abstract classes to:

- Define interfaces to detailed mechanisms and variant parts.
- Implement high-level policies and invariant parts to these interfaces.
- Control sub-class extensions.
- Avoid code duplication.

# Example Application of Template Method

## Functional requirements:

- Need a family of sorting algorithms ... (bubble sort, quick sort, etc.)
- for different kinds of data (int, double, etc.)
- Clients that use sorting algorithms should be reusable with a variety of specific algorithms.

## Non-functional requirements on the design:

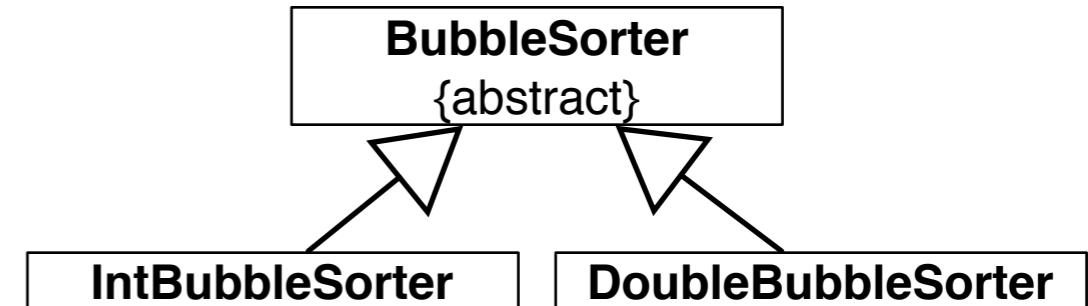

- Need to separate the high-level „sorting“ policies from low-level mechanisms.
- Low-level mechanisms are responsible for:
  - deciding when an element is out of order,
  - swapping out-of-order elements.

# Separating the Policy of Sorting

```
public abstract class BubbleSorter {  
    protected int length = 0;
```

Policy

```
protected void sort() {  
    if (length <= 1) return;  
    for (int nextToLast = length - 2; nextToLast >= 0; nextToLast--)  
        for (int index = 0; index <= nextToLast; index++)  
            if (outOfOrder(index)) swap(index);  
}
```

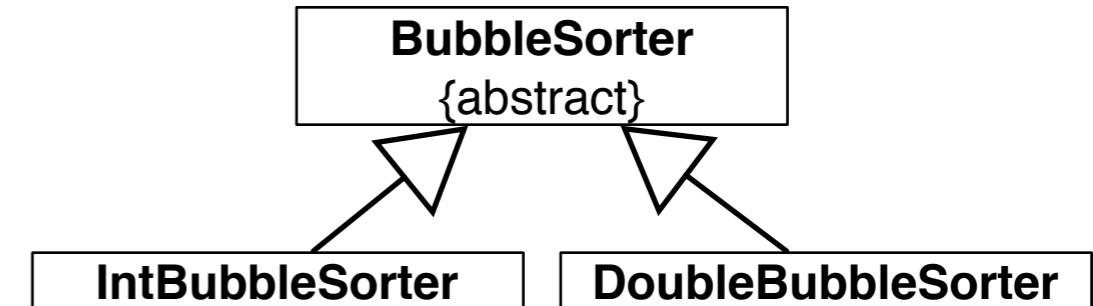

Mechanism

```
protected abstract void swap(int index);  
protected abstract boolean outOfOrder(int index);
```

}

# Filling the Template for Specific Algorithms

```
public class IntBubbleSorter
  extends BubbleSorter {
    private int[] array = null;
    public void sort(int[] theArray) {
        array = theArray;
        length = array.length;
        super.sort();
    }
    protected void swap(int index) {
        int temp = array[index];
        array[index] = array[index + 1];
        array[index + 1] = temp;
    }
    protected boolean outOfOrder(int index) {
        return (array[index] > array[index + 1]);
    }
}
```

What are the advantages and deficiencies of the Template-Method Pattern?

# Template Method Pattern in Log4J

**interface Appender**

Implement this interface for your own strategies for outputting log statements.

[...]

**public void doAppend(LoggingEvent event)**

Log in Appender specific way.

**abstract class AppenderSkeleton implements Appender**

Abstract superclass of the other appenders. This class provides the code for common functionality, such as support for threshold filtering and support for general filters.

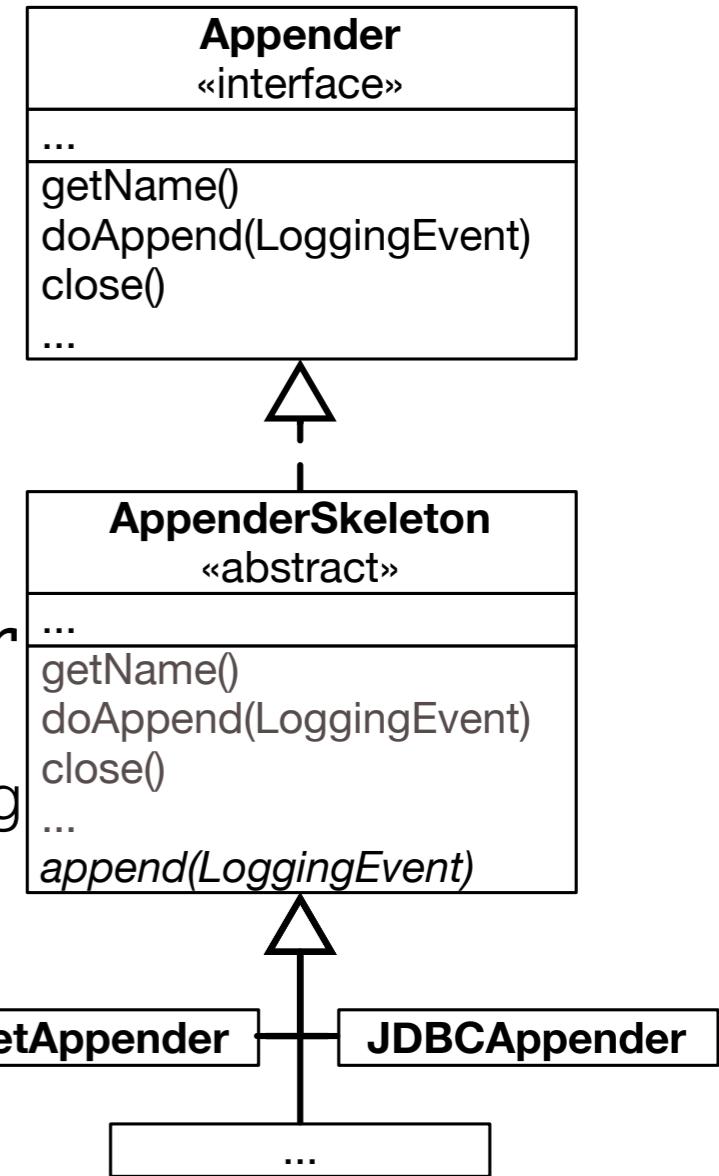

[...]

**protected abstract void append(LoggingEvent event)**

Subclasses should implement this method to perform actual logging.

**public void doAppend(LoggingEvent event)**

This method performs threshold checks and invokes filters before delegating actual logging to the append(LoggingEvent) method.

# Functional Counterpart of Template

---

One can look at the Template-Method Pattern as a style for emulating higher-order functions available in programming languages that support functional-style programming.

---

Alternative design for Log4J in Scala?

```
class AppenderSkeleton{
    private val append : (LoggingEvent) => Unit
} {
    def doAppend(loggingEvent : LoggingEvent) {
        // filtering, threshold checks, ...
        append(loggingEvent)
    }
}
```
