An Introduction to Reactive Programming (2)

Prof. Guido Salvaneschi

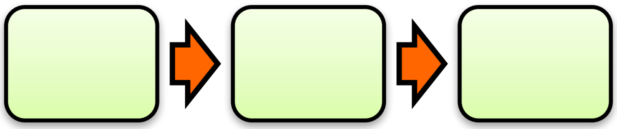
Outline

- Analysis of languages for reactive applications
- Details of reactive frameworks
- Advanced conversion functions
- Examples and exercises
- Related approaches

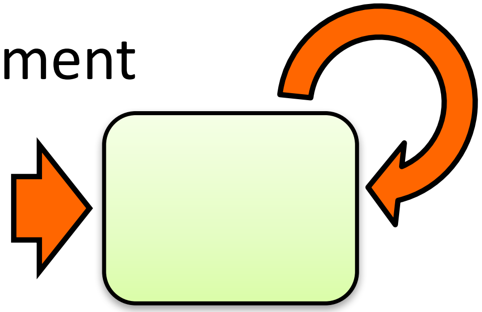
REACTIVE APPLICATIONS: ANALYSIS

Software Taxonomy

- A **transformational** system
  - Accepts input, performs computation on it, produces output, and terminates
  - Compilers, shell tools, scientific computations



- A **reactive** system
  - Continuously interacts with the environment
  - Updates its state



How to implement Reactive Systems ?

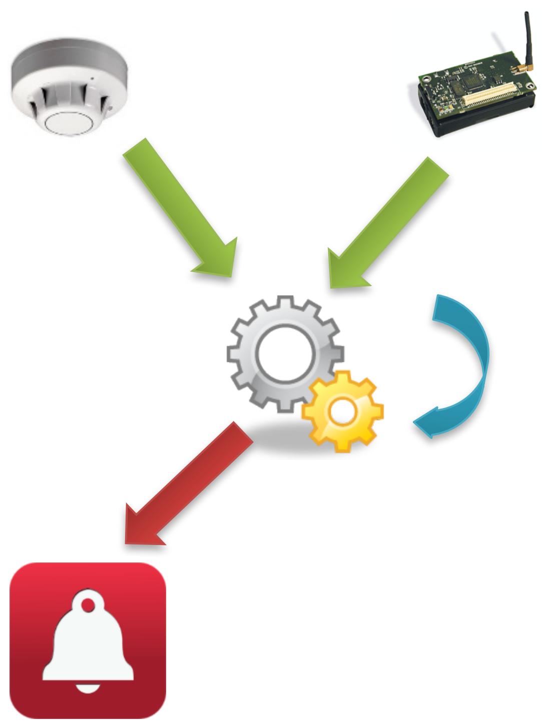
- Observer Patter
  - The *traditional* way in OO languages

- Language-level events
  - Event-based languages

- Signals, vars, events and their combination
  - Reactive languages

OBSERVER PATTERN: ANALYSIS

The (*good*? old) Observer Pattern



```
boolean highTemp;
boolean smoke;

void Init() {
        tempSensor.register(this);
        smokeSensor.register(this);
}

void notifyTempReading(TempEvent e ) {
        highTemp = e.getValue() > 45;
        if (highTemp && smoke) {
                alert.start();
        }
}

void notifySmokeReading(SmokeEvent e) {
        smoke = e.getIntensity() > 0.5;
        if (highTemp && smoke) {
                alert.start();
        }
}
```

State

Registration

Callback functions

Control statements

Callback functions

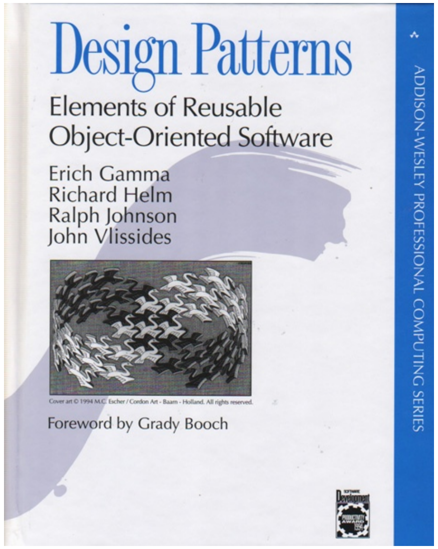
Control statements

Observer for change propagation

- Main advantage:

Decouple the code that changes a value X from the code that updates the values depending on X

  - "Source" doesn't know about "Constraint"
  - Temp/Smoke sensors do not know about fire detector



The (*good*? old) Observer Pattern

- Events are often used to enforce data dependency **constraints**
  - boolean highTemp := (temp.value > 45);

The example

val c = a + b

val a = 3

val b = 7

a = 4

b = 8

The Example: Observer

```
trait Observable {
  val observers = scala.collection.mutable.Set[Observer]()
  def registerObserver(o: Observer) = { observers += o }
  def unregisterObserver(o: Observer) = { observers -= o }
  def notifyObservers(a: Int,b: Int) = { observers.foreach(_.notify(a,b)) }
}
trait Observer {
  def notify(a: Int,b: Int)
}

class Sources extends Observable {
  var a = 3
  var b = 7
}
class Constraint(a: Int, b: Int) extends Observer {
  var c =  a + b
  def notify(a: Int,b: Int) = { c = a + b }
}
```

```
val s = new Sources()
val c = new Constraint(s.a,s.b)
s.registerObserver(c)
s.a = 4
s.notifyObservers(s.a,s.b)
s.b = 8
s.notifyObservers(s.a,s.b)
```

The (*good*? old) Observer Pattern

Long story of criticism…

- Inversion of *natural* dependency order
  - “Sources” updates “Constraint” but in the code “Constraint” calls “Sources” (to register itself)

- Boilerplate code

```
tempSensor.register(this);
smokeSensor.register(this);
```

```
trait Observable {
  val observers = scala.collection.mutable.Set[Observer]()
  def registerObserver(o: Observer) = { observers += o }
  def unregisterObserver(o: Observer) = { observers -= o }
 ….
```

The (*good*? old) Observer Pattern

- Reactions do not compose, return void
  - How to define new constraints based on the existing ones

```
class Constraint(a: Int, b: Int) … {
   var c =  a + b
   def notify(a: Int,b: Int) = {
      c = a + b
} }
```

+

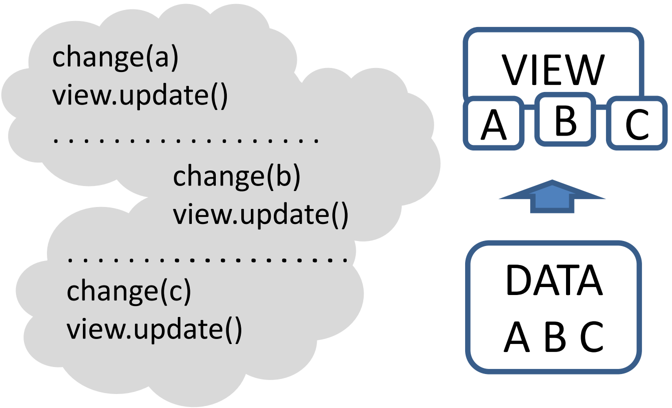
```
class Constraint2(d: Int) … {
   var d =  c * 7
   def notify(d: Int) = {
      d = c * 7
} }
```

= ??

The (*good*? old) Observer Pattern

- Scattering and tangling of triggering code
  - **Fail to update** all functionally dependent values.
  - Values are often update too much (**defensively**)

```
val s = new Sources()
val c = new Constraint(s.a,s.b)
s.registerObserver(c)
s.a = 4
s.notifyObservers(s.a,s.b)
s.b = 8
s.notifyObservers(s.a,s.b)
```



The (*good*? old) Observer Pattern

- Imperative updates of state

```
class Constraint(a: Int, b: Int) extends Observer {
   var c =  a + b
   def notify(a: Int,b: Int) = { c = a + b }
 }
```

- No separation of concerns

```
class Constraint(a: Int, b: Int) extends Observer {
   var c =  a + b
   def notify(a: Int,b: Int) = { c = a + b }
 }
```

Update logic
+
Constraint definition

EVENT-BASED LANGUAGES: ANALYSIS

Event-based Languages

- Language-level support for events
  - C#, Ptolemy, REScala, …

```
val e = Evt[Int]()
e += { println(_) }
e(10)
```

  - Imperative events

```
val update = Evt[Unit]()
```

  - Declarative events, ||, &&, map, …

```
val changed[Unit] = resized || moved || afterExecSetColor
val invalidated[Rectangle] = changed.map( _ => getBounds() )
```

Event-based Languages

```
val update = Evt[Unit]()
val a = 3
val b = 7
val c = a + b  // Functional dependency

update += ( _ =>{
  c = a + b
})

a = 4
update()
b = 8
update()
```

Event-based Languages

- More composable
  - Declarative events are composed by existing events (not in the example)
- Less boilerplate code
  - Applications are easier to understand

- Good integration with Objects and imperative style:
  - Imperative updates and side effects
  - Inheritance, polymorphism, …

Event-based Languages

- Dependencies still encoded manually
  - Handler registration
- Updates must be implemented explicitly
  - In the handlers
- Notifications are still error prone:
  - Too rarely / too often

```
class Connector(val start: Figure, val end: Figure) {
   start.changed += updateStart
   end.changed += updateEnd
 ...
   def updateStart() { ... }
   def updateEnd() { ... }
 ...
```

REACTIVE LANGUAGES: ANALYSIS

Reactive Languages

- Functional-reactive programming (FRP) -- Haskell
  - **Time-changing values** as dedicated language abstractions.
    [Functional reactive animation, Elliott and Hudak. ICFP '97]

- More recently:
  - FrTime *[Embedding dynamic dataflow in a call-by-value language, Cooper and Krishnamurthi, ESOP'06]*
  - Flapjax *[Flapjax: a programming language for Ajax applications. Meyerovich et al. OOPSLA'09]*
  - Scala.React *[I.Maier et al, Deprecating the Observer Pattern with Scala.React. Technical report, 2012]*

Reactive Languages and FRP

- Signals
  - Dedicated language abstractions for **time-changing** values

```
val a = Var(3)
val b = Var(7)
val c = Signal{ a() + b() }

println(c.now)
> 10
a()= 4
println(c.now)
> 11
```

- An alternative to the Observer pattern and inversion of control

```
/* Create the graphics */
title = "Reactive Swing App“
val button = new Button {
  text = "Click me!"
}
val label = new Label {
  text = "No button clicks registered"
}
contents = new BoxPanel(Orientation.Vertical) {
  contents += button
  contents += label
}
```

```
/* The logic */
listenTo(button)
var nClicks = 0
reactions += {
  case ButtonClicked(b) =>
    nClicks += 1
    label.text = "Number of button clicks: " + nClicks
    if (nClicks > 0)
      button.text = "Click me again"
}
```

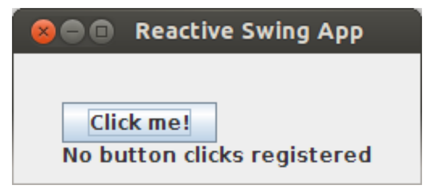
```
title = "Reactive Swing App"
val label = new ReactiveLabel
val button = new ReactiveButton

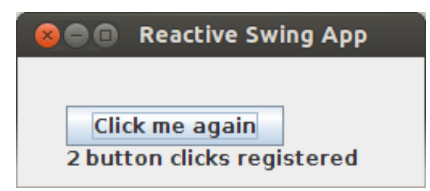
val nClicks = button.clicked.fold(0) {(x, _) => x + 1}

label.text = Signal { ( if (nClicks() == 0) "No" else nClicks() ) + " button clicks registered" }

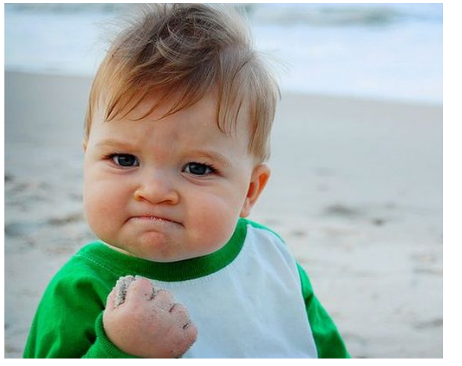
button.text = Signal { "Click me" + (if (nClicks() == 0) "!" else " again " )}

contents = new BoxPanel(Orientation.Vertical) {
    contents += button
    contents += label
}
```





Reactive Languages



- Easier to understand
  - Declarative style
  - Local reasoning
  - No need to follow the control flow to reverse engineer the constraints
- Dependent values are automatically consistent
  - No boilerplate code
  - No update errors (no updates/update defensively)
  - No scattering and tangling of update code
- Reactive behaviors are composable
  - In contrast to callbacks, which return void

NOW…

Signals allow a good design.
But they are *functional* (only).

```
val a = Var(3)
val b = Var(7)
val c = Signal{ a() + b() }
val d = Signal{ 2 * c() }
val e = Signal{ "Result: " + d() }
```

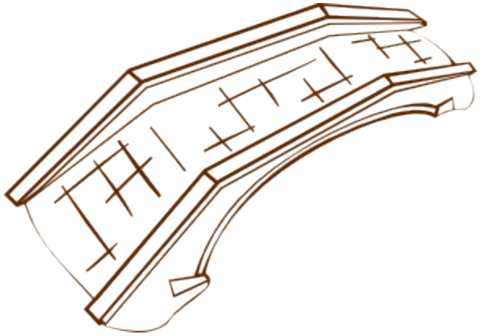
Functional programming is great! But…

The sad story:

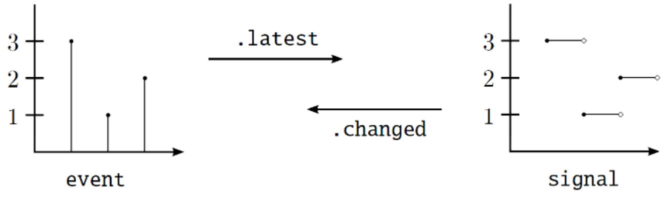
- The world is **event-based**, …
- Often **imperative, …**
- And mostly **Object-oriented**

Reactive Languages

- In practice, both are supported:
  - Signals (continuous)
  - Events (discrete)
- Conversion functions
  - Bridge signals and events
  - Allow interaction with objects state and imperative code



```
Changed :: Signal[T] -> Event[T]
Latest :: Event[T] -> Signal[T]
```



ADVANCED INTERFACE FUNCTIONS

Fold

- Creates a signal by folding events with a function f
  - Initially the signal holds the **init** value.
- fold[T,A](e: Event[T], init: A)(f :(A,T)=>A): Signal[A]

```
val e = Evt[Int]()
val f = (x:Int,y:Int)=>(x+y)
val s: Signal[Int] = e.fold(10)(f)
assert(s.now == 10)
e(1)
e(2)
assert(s.now == 13)
```

LatestOption

- Variant of latest.
  - The Option type for the case the event did not fire yet.
  - Latest value of an event as Some(value) or None
- latestOption[T](e: Event[T]): Signal[Option[T]]

```
val e = Evt[Int]()
val s: Signal[Option[Int]] = e.latestOption(e)
assert(s.now == None)
e(1)
assert(s.now == Option(1))
e(2)
assert(s.now == Option(2))
e(1)
assert(s.now == Option(1))
```

Last

- Generalizes **latest**
  - Returns a signal which holds the last **n** events
  - Initially an empty list
- last[T](e: Event[T], n: Int): Signal[List[T]]

```
val e = Evt[Int]()
val s: Signal[List[Int]] = e.last(5)

assert(s.now == List())
e(1)
assert(s.now == List(1))
e(2)
assert(s.now == List(2,1))
```

```
e(3);e(4);e(5)
assert(s.now == List(5,4,3,2,1))
e(6)
assert(s.now == List(6,5,4,3,2))
```

List

- Collects the event values in a (ever growing) list
- Use carefully… potential memory leaks

- list[T](e: Event[T]): Signal[List[T]]

Iterate

- Repeatedly applies **f** to a value when e occurs
  - The return signal is constant, based on init
  - F is similar to a handler
- iterate[A](e: Event[_], init: A)(f: A=>A) :Signal[A]

```
var test: Int = 0
val e = Evt[Int]()
val f = (x:Int)=>{test=x; x+1}
val s: Signal[Int] = e.iterate(10)(f)
```

```
e(1)
assert(test == 10)
assert(s.now == 10)
e(2)
assert(test == 11)
assert(s.now == 10)
e(1)
assert(test == 12)
assert(s.now == 10)
```

Count

- Returns a signal that counts the occurrences of e
  - Initially, the signal holds 0.
  - The argument of the event is discarded.
- count(e: Event[_]): Signal[Int]

```
val e = Evt[Int]()
val s: Signal[Int] = e.count
assert(s.now == 0)
e(1)
e(3)
assert(s.now == 2)
```

Snapshot

- Returns a signal updated only when **e** fires.
  - Other changes of **s** are ignored.
  - The signal is updated to the current value of **s**.
  - Returns the signal itself before **e** fires
- snapshot[V](e : Event[_], s: Signal[V]): Signal[V]

```
val e = Evt[Int]()
val v =  Var(1)
val s1 = Signal{ v() + 1 }
val s = e.snapshot(s1)

        s!?
```

```
assert(s.now == 2)
e(1)
assert(s.now == 2)
v.set(2)  // s1 == 3
assert(s.now == 2)
e(1)
assert(s.now == 3)
```

Change

- Similar to changed
  - changed[U]: Event[U]
  - Provides both the old and the new value in a tuple
  - change[U]: Event[Diff[U]]

```
val s = Signal{ ... }
val e: Event[Diff[Int]] = s.change
e += (x: Diff[Int]=> {
  val (old,nnew): (Int,Int) = x.pair
    ...

})
```

ChangedTo

- Similar to changed
  - The event is fired only if the signal holds the given value
  - The value of e is discarded
- changedTo[V](value: V): Event[Unit]

```
var test = 0
val v =  Var(1)
val s = Signal{ v() + 1 }
val e: Event[Unit] = s.changedTo(3)
e += ((x:Unit)=>{test+=1})
```

```
assert(test == 0)
v set 2
assert(test == 1)
v set 3
assert(test == 1)
```

test !?

Toggle

- Switches between signals on the occurrence of e.
  - The value attached to the event is discarded
  - toggle[T](e : Event[_], a: Signal[T], b: Signal[T]): Signal[T]

```
val e = Evt[Int]()
val v1 =  Var(1)
val s1 = Signal{ v1() + 1 }
val v2 =  Var(11)
val s2 = Signal{ v2() + 1 }
val s = e.toggle(s1,s2)
```

S !?

```
assert(s.now == 2)
e(1)
assert(s.now == 12)
v2.set(12)
assert(s.now == 13)
v1.set(2)
assert(s.now == 13)
e(1)
v1.set(3)
assert(s.now == 4)
v2.set(13)
assert(s.now == 4)
```

switchOnce

- Switches to a new signal provided as a parameter once, on the occurrence of e

switchOnce[T]

(e: Event[_], original: Signal[T], newSignal: Signal[T]): Signal[T]

```
val e = Evt[Int]()
val v1 =  Var(0)
val v2 =  Var(10)
val s1 = Signal{ v1() + 1 }
val s2 = Signal{ v2() + 1 }
val s3 = e.switchOnce(s1,s2)
```

```
assert(s3.now == 1)
v1.set(1)
assert(s3.now == 2)
e(1)
assert(s3.now == 11)
e(2)
v2.set(11)
assert(s3.now == 12)
```

Note on the interface

- We showed the “non OO” signature for most of the interface functions
  - In practice, the signature is in OO style
  - One of the parameters is the receiver of the method

- For example

```
snapshot(e,s)    // snapshot[V](e : Event[_], s: Signal[V]): Signal[V]
```

  - Must be called as:

```
e.snapshot(s)    // e.snapshot[V](s: Signal[V]): Signal[V]
```

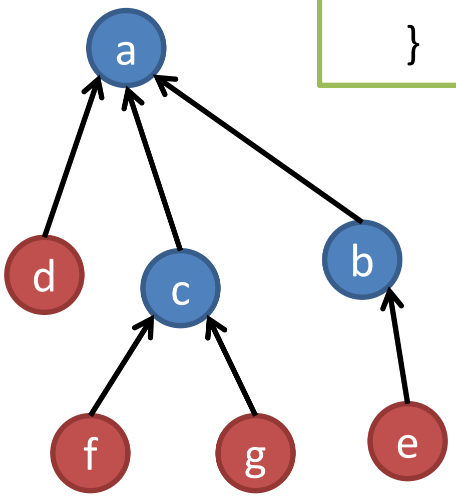
DETAILS ON THE REACTIVE MODEL

Implementation: Challenges

- In-language reactive abstractions
  - DSL/Compiler
  - Build the dependency model
- Language runtime
  - Dependency graph
    - Evaluation
    - Change propagation
    - Model maintenance

```
val e, f, g = Var(1)
val d = Var(true)

c = Signal { f() + g() }
b = Signal { e() * 100 }
a = Signal {
        if (d) c
        else b
    }
```

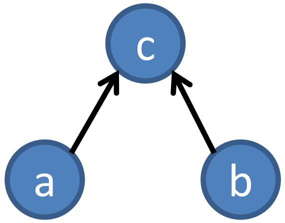


DSL Implementation

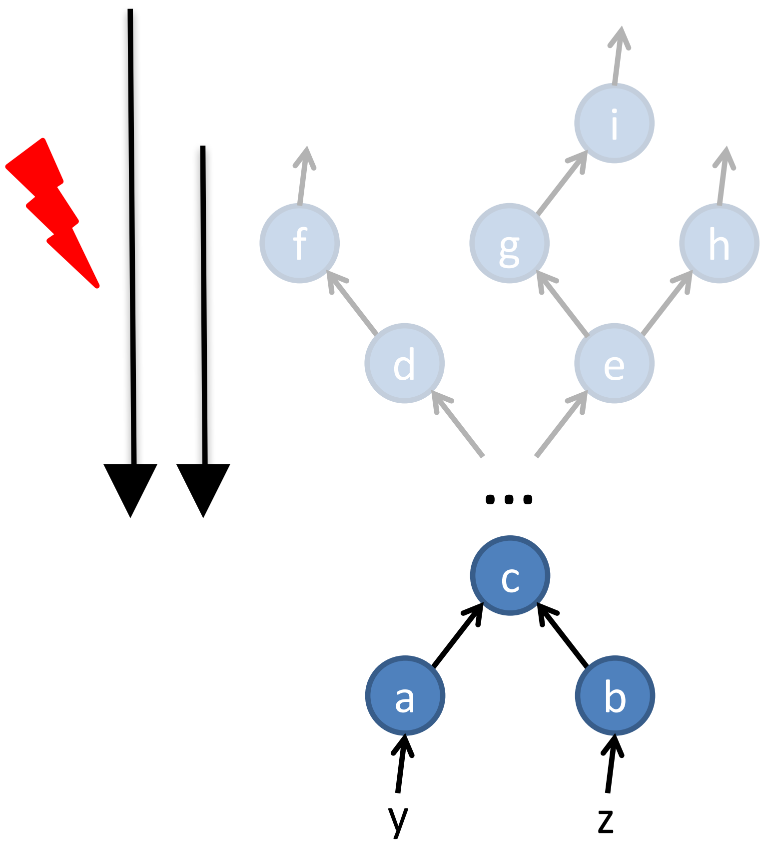
- Building the graph
  - Var(3) -> leaf
  - Var(4) -> leaf
  - “a() + b()” saved in a closure
  - Signal{…} -> dependent node

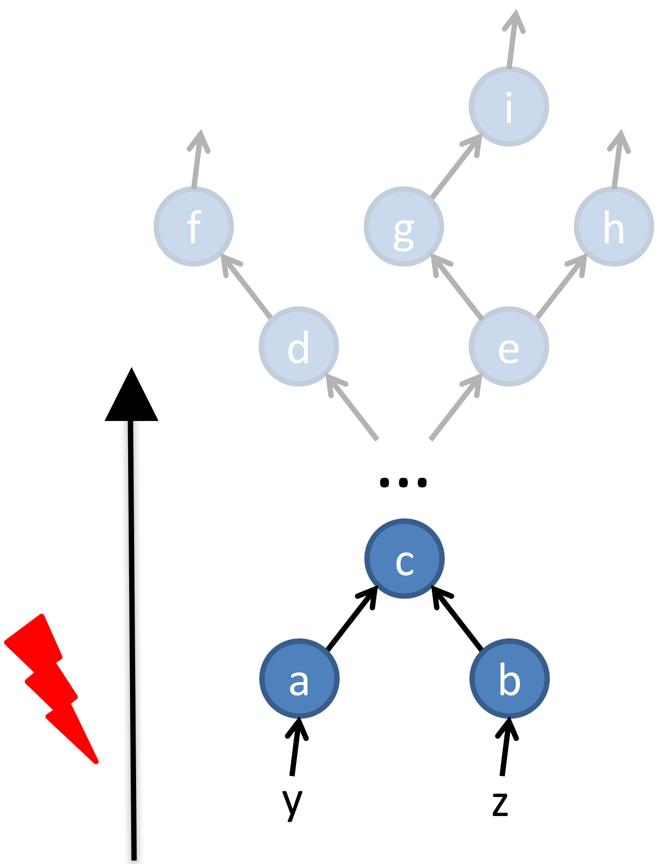
```
val a = Var(3)
val b = Var(4)
val c = Signal { a() + b() }
```

- Signal expression evaluation
  - Reactive values -> edges
  - Signal = result of the evaluation



Pull vs. Push Models





E.g., REScala, Rx, bacon.js

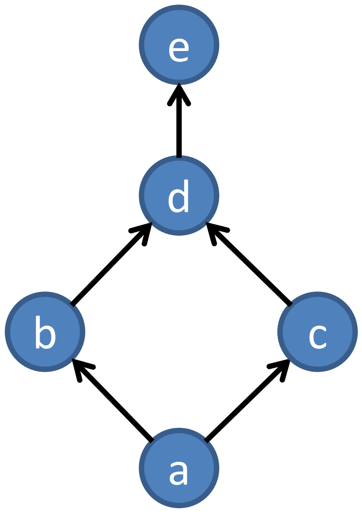
Glitches

Temporary *spurious* values due to propagation order.

– Update order abdc

– a()=2 b<-4, d<-7, c<-6, d<-10

```
val a = Var(1)
val b = Signal{ a()*2 }
val c = Signal{ a()*3 }
val d = Signal{ b() + c() }
val e = d.changed
```

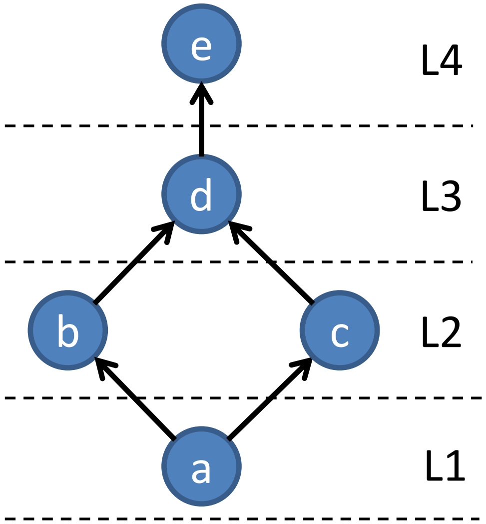


- Effects:
  – d redundantly evaluated 2 times
  – First value of d has *no meaning*
  – e erroneously fired two times

Glitch Freedom

- Ensured by updates *in topological order*
  - Nodes are assigned to levels **Ln**
  - Levels are updates in order
  - E.g., "abcde" or "acbde"

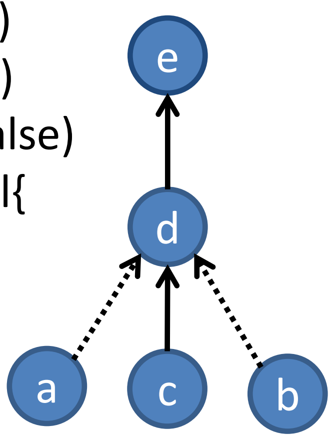
- Technical solutions:
  - Priority queue
  - Nodes wait for children before evaluating



Dynamic dependencies

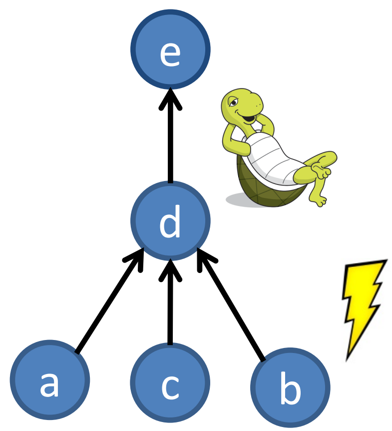
- Dependencies based on runtime conditions
  - In case *c==true*, *d* must change:
    - If *a* changes
    - Not if *b* changes
  - *d* depends on *a* or *b*
    based on current value of *c*
  - Change dependencies at runtime

```
val a = Var(3)
val b = Var(7)
val c = Var(false)
val d = Signal{
  if c()
    a()
  else
    b()
}
val e = Signal { 2 * d() }
```



(Lack of) Dynamic dependencies

- Easier implementation
- Redundant evaluations
  - d is executed upon b assignments
  - even if the d does not change



```
val a = Var(3)
val t = Var(7)
val c = Var(true)
val d = Signal{
  if c()
    a()
  else
    b()
}
while(true){
  b()= … // system time
}
```

About Loops

- Reject loops
  - Responsibility to the programmer (REScala, Flapjax)
  - Loops rejected by the compiler
- Accept loops: which semantics ?
  - Delay to the next propagation round
  - Fix point semantics
    - Time consuming ?
    - Termination ?

```
val x = Signal { y() + 1 }
val y = Signal { x() + 1 }
```

EXAMPLES AND EXERCISES

Example: Interface Functions

- Count mouse clicks

```
val click: Event[(Int, Int)] = mouse.click
val nClick = Var(0)
click += { _ =>
  nClick.transform(_ + 1)   // nClick() = nClick.now +1
}
```

- Better with interface functions

```
val click: Event[(Int, Int)] = mouse.click
val nClick: Signal[Int] = click.fold(0)( (x, _ ) => x+1 )
```

- Even better: use *count*!

```
val click: Event[(Int, Int)] = mouse.click
val nClick: Signal[Int] = click.count()
```

Conciseness
vs.
Generality

Example: Interface Functions

- Hold the position of the last click in a signal

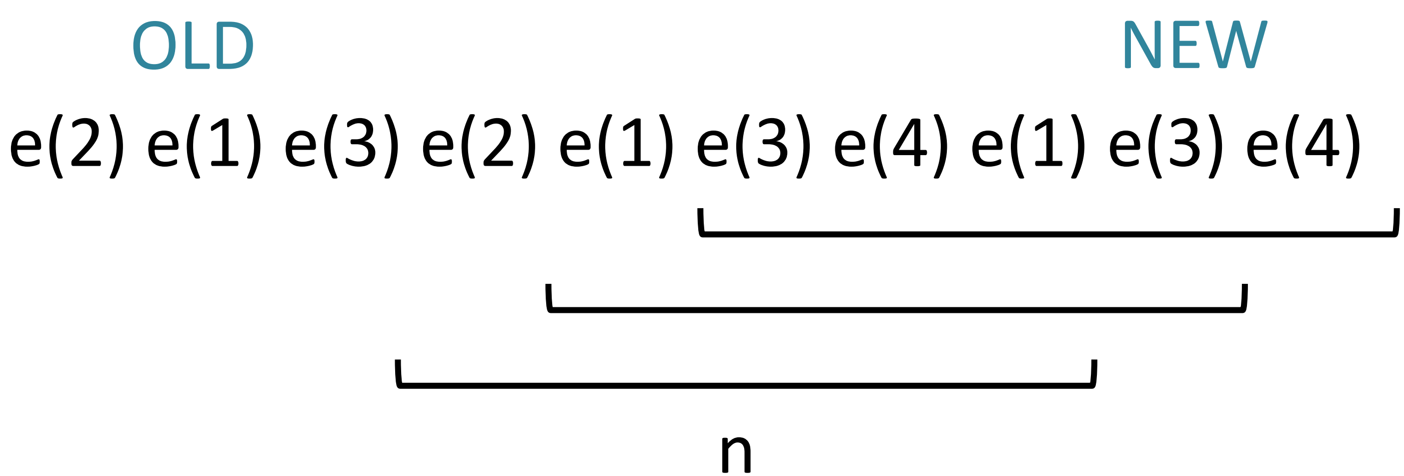
```
val clicked: Event[Unit] = mouse.clicked
val position: Signal[(Int,Int)] = mouse.position
var lastClick = Var(0,0)
clicked += { _ =>
  lastClick()= position()
}
```

- Better with interface functions

```
val clicked: Event[Unit] = mouse.clicked
val position: Signal[(Int,Int)] = mouse.position
val lastClick: Signal[(Int,Int)] = position snapshot clicked
```

Mean Over Window

- Events collect *Double* values from a sensor
- Mean over a shifting window of the last n events
- Print the mean only when it changes



Mean Over Window

- Mean over a shifting window of the last n events
- Print the mean only when it changes

```
val e = Evt[Double]

val window = e.last(5)
val mean = Signal {  window().sum / window().length }
mean.changed += {println(_)}

e(2); e(1); e(3); e(4); e(1); e(1)
```

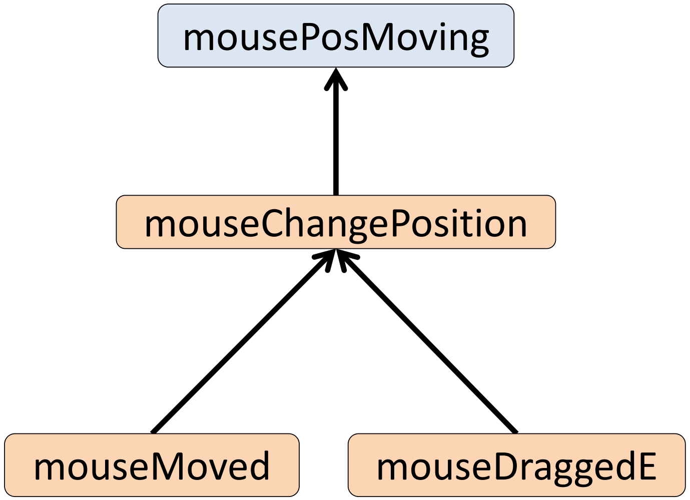
```
2.0
1.5
2.0
2.5
2.2
2.0
```

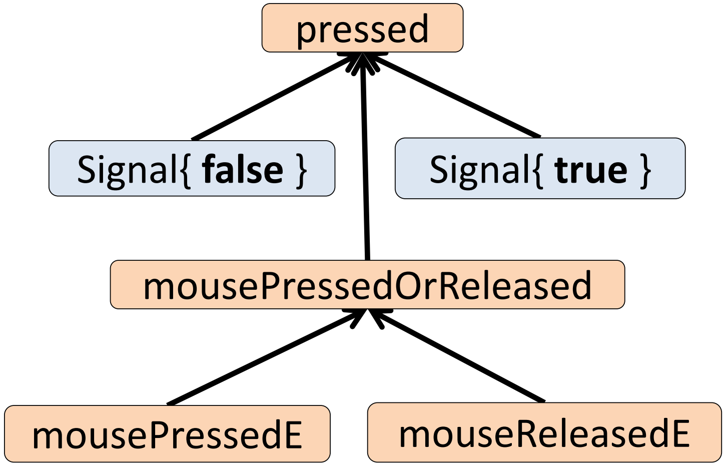
Example: Interface Functions

```
/* Compose reactive values */
val mouseChangePosition = mouseMovedE || mouseDraggedE
val mousePressedOrReleased = mousePressedE || mouseReleasedE
val mousePosMoving: Signal[Point] = mouseChangePosition.latest( new Point(0, 0) )
val pressed: Signal[Boolean] = mousePressedOrReleased.toggle( Signal{ false }, Signal{ true } )
```

Dependency Graph

```
/* Compose reactive values */
val mouseChangePosition = mouseMovedE || mouseDraggedE
val mousePressedOrReleased = mousePressedE || mouseReleasedE
val mousePosMoving: Signal[Point] = mouseChangePosition.latest( new Point(0, 0) )
val pressed: Signal[Boolean] = mousePressedOrReleased.toggle( Signal{ false }, Signal{ true } )
```





Example: Time Elapsing

- We want to show the elapsing time on a display
- (second,minute,hour,day)

(0,0,0,0)	(1,2,0,0)
(1,0,0,0)	…
(2,0,0,0)	(59,59,0,0)
…	(0,0,1,0)
(59,0,0,0)	…
(0,1,0,0)	(59,59,23,0)
(1,1,0,0)	(0,0,0,1)
(2,1,0,0)	….
…	
(59,1,0,0)	
(0,2,0,0)	

Time Elapsing: First Attempt

```
object TimeElapsing extends App {

  println("start!")

  val tick = Var(0)
  val second = Signal{ tick() % 60 }
  val minute = Signal{ tick()/60 % 60 }
  val hour = Signal{ tick()/(60*60) % (60*60) }
  val day = Signal{ tick()/(60*60*24) % (60*60*24) }

  while(true){
    Thread.sleep(0)
    println((second.now, minute.now, hour.now, day.now))
    tick.set(tick.now + 1)
  }
}
```

But day is still circular.
At some point day==0 again

Also, conceptually hard to follow

Time Elapsing

```
object AdvancedTimeElapsing extends App {
 println("start!")
 val tick = Evt[Unit]()

 val numTics = tick.count
 val seconds =  Signal{ numTics() % 60 }
 val minutes = Signal{ seconds.changedTo(0).count.apply % 60 }
 val hours =  Signal{ minutes.changedTo(0).count.apply % 24 }
 val days =  hours.changedTo(0).count

 while(true){
  Thread.sleep(0)
  println((seconds.now, minutes.now, hours.now, days.now))
  tick(())  // tick.fire()
 }
}
```

Use

s.changedTo(v)

- Fires and event if s holds v

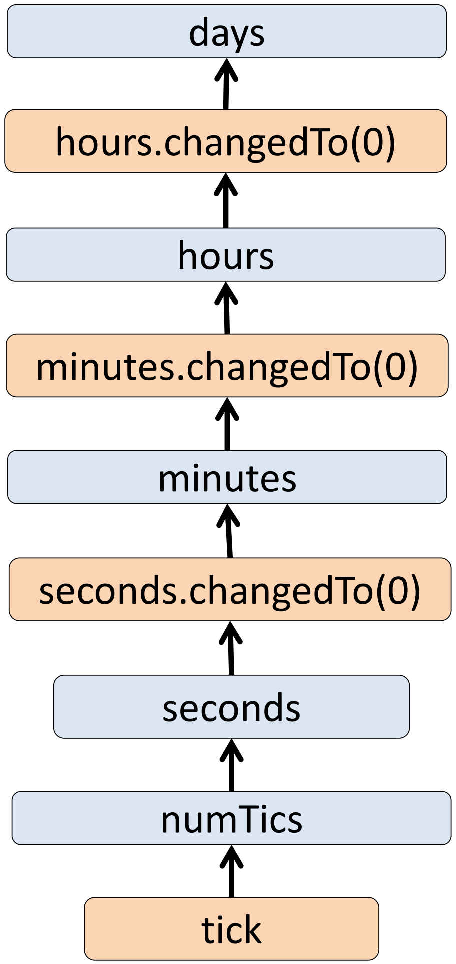
e.count

- Counts the occurrences of e

Exercise: draw dependency graph

```
val tick = Evt[Unit]()
val numTics = tick.count
val seconds = Signal{ numTics() % 60 }
val minutes = Signal{ seconds.changedTo(0).count() % 60 }
val hours = Signal{ minutes.changedTo(0).count() % 24 }
val days = hours.changedTo(0).count
```

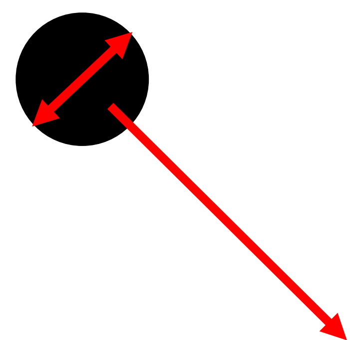
- Which variables are affected by a change to tick ?



(Some nodes omitted)

Example: Smashing Particles

- Particles
  - Get bigger
  - Move bottom-right



```
val toDraw = ListBuffer[Function1[Graphics2D,Unit]]()
 type Delta = Point

 class Oval(center: Signal[Point], radius: Signal[Int]) {
  toDraw += ((g: Graphics2D) =>
   {g.fillOval(center.now.x,center.now.y, radius.now, radius.now)})
 }

 val base = Var(0)
 val time = Signal{base() % 200} // time is cyclic :)

 val point1 = Signal{ new Point(20+time(), 20+time())}
 new Oval(point1, time)
 val point2 = Signal{ new Point(40+time(), 80+time())}
 new Oval(point2, time)
  …
```

```
override def main(args: Array[String]){
  while (true) {
     frame.repaint
     Thread sleep 20
     base()= base.now + 1
 }}
```

- Signals are used inside objects!

QUESTIONS?

Training with RP - Resources

- Examples in the lecture slides
  - Observer
  - Reactive programming
- Homework assignments
- REScala examples (online, RP and OO version)
- REScala manual (online)

…becoming Very Popular

Java 8

```
List<String> l = Arrays.asList("a1", "c2", "b1", "c2");
 l.stream()
   .filter(s -> s.startsWith("c"))
   .map(String::toUpperCase)
   .sorted()
   .collect(Collectors.toList)
```

ReactiveX

```
getDataFromNetwork()
  .skip(10)
  .take(5)
  .map({ s -> return s + " transformed" })
  .subscribe({ println "onNext => " + it })
```

Apache Spark

```
TwitterUtils.createStream(...)
    .filter(_.getText.contains("Spark"))
    .countByWindow(Seconds(5))
```
